# Growth and the Fragmentation of Production

Johannes Boehm <sup>1</sup> Ezra Oberfield <sup>2</sup>

ESSEC/Thema

October 20, 2022

<sup>1</sup>Sciences Po <sup>2</sup>Princeton

#### Motivation

Since Adam Smith, economists have been postulating a link between specialization and productivity:

"The greatest improvement in the productive powers of labour [...] seem to have been the effects of the division of labour." (Wealth of Nations, Chapter 1, 1776)

In the context of supply chains: how is value chain broken down into work done by different plants?

2

#### Motivation

Since Adam Smith, economists have been postulating a link between specialization and productivity:

"The greatest improvement in the productive powers of labour [...] seem to have been the effects of the division of labour." (Wealth of Nations, Chapter 1, 1776)

In the context of supply chains: how is value chain broken down into work done by different plants?

**This paper:** specialization in value chain *among plants* and growth. E.g. do plants produce shirts from cloth or from yarn?

- 1. Empirical facts about organization and performance using manufacturing data from India
  - · macro: vertical specialization  $\Leftrightarrow$  income per capita
  - micro: vertical specialization ⇔ plant size
- 2. Model: positive predictions, implications for growth

#### Literature

#### Specialization and productivity:

- Theory: Young (1928), Stigler (1951), Rosen (1978), Baumgardner (1988), Becker and Murphy (1992), Rodriguez-Clare (1996), Akerman and Py (2010), Chaney and Ossa (2013), Limao and Xu (2021)
- Empirical evidence: Baumgardner (1988), Brown (1992), Garicano and Hubbard (2009), Duranton and Jayet (2011), Tian (2018), Hansman et al. (2020), Chor et al. (2020), Bergeaud et al. (2021), Bartelme et al. (2021), Atalay, Sotelo, and Tannenbaum (2021)

#### Smithian Growth:

• Boreland and Yang (1991), Kelly (1997), Legros, Newman, Proto (2014), Menzio (2020)

#### Indian Trade Liberalization:

 Panagariya (2004), Sivadasan (2009), Khandelwal and Topalova (2010), Goldberg et al. (2010), Peter and Ruane (2020)

#### Input-Output Structure and Growth:

· Ciccone (2002), Boehm (2022), Boehm and Oberfield (2020), Acemoglu and Azar (2020), Chenery et al (1986), Jones (2013), Fadinger, Ghiglino, and Teteryatnikova (2021), Bartelme and Gorodnichenko (2015)

#### **Endogenous Production Networks:**

 Oberfield (2018), Eaton, Kortum, Kramarz (2022), Lim (2018), Chaney (2014), Dhyne et al (2021), Startz (2021), Grant and Startz (2021), Taschereau-Dumochel (2017), Huneeus (2018), Miyauchi (2018), Panigrahi (2021)

#### Manufacturing Plants in India

Data: Indian Annual Survey of Industries, 1989/90-2014/15 (with gaps)

- · Plant-level panel survey of formal manufacturing plants
  - All plants that have 100+ employees
  - 1/5 of all plants between 20 (10 if using power) and 100 employees

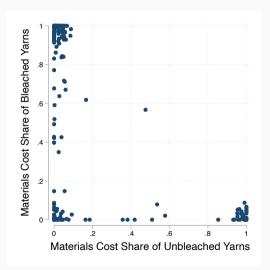

Most important part of the survey:

 Quantities, unit values & 5-digit product codes for all manufacturing output and intermediate inputs (domestic and imported)

Example product codes: Silk yarn, bleached (61222), beryllium copper wire (72246), aluminium ingots (73107)

	min	p25	p50	p75	max	count
Multi-product	1	1	3	5	117	235,566
Single-product	1	1	2	4	69	359,894
Total	1	1	3	5	117	595,460

## Within narrow industries, firms use different inputs

Materials Cost Share of Cut Diamonds Materials Cost Share of Rough Diamonds

(a) Input mixes for Bleached Cotton Cloth (63303)

(b) Input mixes for Polished Diamonds (92104)

#### Measuring the vertical span of production (Boehm & Oberfield, 2020)

Fix an output industry.

- 1. **Vertical Distance of Input from Output** in supply chain: is input close or far from output?
  - · Similar to upstreamness of Alfaro et al. (2019)

2. Vertical Span of Plant: Does shirt producer use inputs that are distant or close?

$$\mathrm{span}_{jt} = \sum_{\hat{\Omega}} \frac{X_{j\hat{\omega}}}{\sum_{\tilde{\omega}} X_{j\tilde{\omega}}} d_{\omega\hat{\omega}}$$

## Vertical Distance of inputs from output – Examples

Table 1: Vertical distance examples for 63428: Cotton Shirts

	Mean Vertical Distance
Fabrics/Cloths	1.66
Yarns	2.58
Ginned & pressed cotton	3.44
Raw cotton	4.09

Table 2: Vertical distance examples for 73107: Aluminium Ingots

	Vertical Distance
Anodes, copper	1.00
Aluminium scrap	1.19
Aluminium oxide	1.25
Bauxite, calcined	2.18
Caustic soda (sodium hydroxide)	2.39
Bauxite, raw	3.03
Coal	3.43

# Long and short vertical span

Figure 1: Input mixes for Polished Diamonds (92104)

Motivational Facts about Vertical

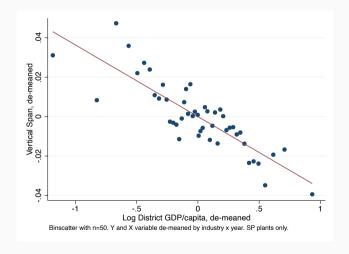

Specialization

## Macro facts: Vertical specialization is positively correlated with development

Within industry × year:

Plants in **richer districts** are on average **more vertically specialized** 

Holds in the **time dimension**:
In Indian states that grew faster,
plants vert. specializing more

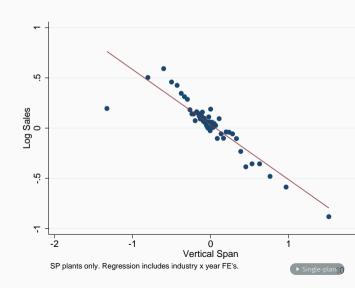

## Micro facts: Vertical specialization is positively correlated with plant size

Within industry  $\times$  year:

Plants with **higher sales** tend to have **shorter vertical span** 

Holds also in the **time dimension**: Plants that v. specialize more grow faster • show

#### Indian Trade Liberalization to get at causality

- · Until end of 80s: India in near-autarky
  - Import licensing system
  - $\cdot$  Very high tariffs. Large variation (up to 355%), average  $\sim$ 80%. Was set in the 1950s.
- **July 1991:** Balance of Payments crisis. Removal of import licensing system, starts cutting tariffs.
- 1992-1997: Tariffs come down to average of 35%, ending up fairly uniform.
- $\cdot \Rightarrow$  tariff change was determined in the 50's
- ⇒ tariff changes are uncorrelated with 1992 industry characteristics (Khandelwal and Topalova, 2010: "as exogenous to the state of the industries as a researcher might hope for").

See also Panagariya (2004), Sivadasan (2009), Khandelwal and Topalova (2010), Goldberg et al. (2010).

#### Other empirical results

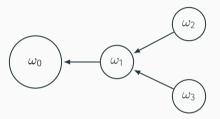

· Tariff supply & demand shocks affect entry. Lower output tariffs decreases the number of plants Lower input tariffs increases the number of plants.

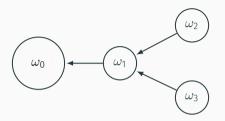

· Input tariffs affect input adoption. Lower input tariffs lead to an increased probability of plants using that input.

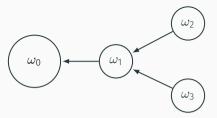

Simple Model

- · Buying  $\omega_1$  from a supplier ('shirts from cloth')
- $\cdot$  Buying  $\omega_2$  and  $\omega_3$  from suppliers ('shirts from yarn & dye')

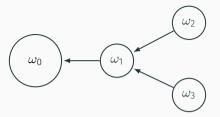

#### 1. Buying $\omega_1$ from a supplier ('shirts from cloth')

Firms search for  $\omega_1$  suppliers. Search effort  $h_1$ .

Cost of production: 
$$c_{j\omega_0} = \frac{1}{q_j} w^{\alpha_l^0} \left( \tilde{c}_j^1 \right)^{1-\alpha_l^0}$$
  $\tilde{c}_j^1 = \min_{s \in S_j^1} \frac{\text{price}_s}{\text{match-specific prod}_{js}}$ 

Arrival rate of supplier matches + match-specific productivity so that  $\tilde{c}_j^1 \sim \text{EV}(h_1 v_1, \zeta)$ 

#### 2. Buying $\omega_2$ and $\omega_3$ from suppliers ('shirts from yarn & dye')

Firms search for  $\omega_2, \omega_3$  suppliers. Search efforts  $h_2, h_3$ 

Cost of production: 
$$c_{j\omega_0} = \frac{1}{q_j} w^{\alpha_l^0} \left( \underbrace{\frac{1}{b_j} w^{\alpha_l^1} (\tilde{c}_j^2)^{\alpha_2^1} (\tilde{c}_j^3)^{\alpha_3^1}}_{\sim EV \left( (h_2 v_2)^{\alpha_2^1} (h_3 v_3)^{\alpha_3^1}, \zeta \right)} \right)^{1-\alpha_l^0}$$

$$\tilde{c}_j^2 \sim EV(h_2 v_2, \zeta), \qquad \tilde{c}_j^3 \sim EV(h_3 v_3, \zeta), \qquad \chi(\log b_j) = \frac{\Gamma(1 - \zeta it)}{\Gamma(1 - \alpha_2^1 \zeta it)\Gamma(1 - \alpha_3^1 \zeta it)}$$

#### Search problem

- Firm born with productivity  $q_i$ , make search choice based only on that.
- · Profits from sales to households, isoelastic demand, isoelastic search costs:

$$\max_{\{h\}_{i}} \quad \mathbb{E}\left(\pi_{j}|q_{j},\{h\}_{i}\right) - \sum_{i=1,2,3} \frac{k}{1+\gamma} h_{i}^{1+\gamma}$$

$$A_{\omega_{0}} q^{\varepsilon-1} \mathbb{E}\left(c_{j}|q_{j},\{h\}_{i}\right)^{1-\varepsilon} - \sum_{i=1,2,3} \frac{k}{1+\gamma} h_{i}^{1+\gamma}$$

$$A_{\omega_{0}} q^{\varepsilon-1} \left[h_{1} v_{1} + (h_{2} v_{2})^{\alpha_{2}^{1}} (h_{3} v_{3})^{\alpha_{3}^{1}}\right]^{(1-\alpha_{i}^{0}) \frac{\varepsilon-1}{\zeta}} - \sum_{i=1,2,3} \frac{k}{1+\gamma} h_{i}^{1+\gamma}$$

- Nonhomotheticity: return from searching in upstream industries (i.e. 2, 3) is more concave than in downstream industry (1).
  - $\Rightarrow$  Plants born with high q will be more likely to be vertically specialized (use  $\omega_1$  rather than  $\omega_2, \omega_3$ ). Size  $\leftrightarrow$  Span relationship in the data

## Nonhomotheticity

- $\cdot$  A firm with a higher Hicks-neutral productivity  $q_i$  will search more in all markets
- But if the elasticity of substitution across nests is higher than within nests then  $\log h_1 \nearrow$  more than  $\log h_2 \nearrow$  (or  $\log h_3 \nearrow$ ).
  - Why? When organizational forms are substitutable,  $x_{\omega_1}$  is more elastic than  $(x_{\omega_2}, x_{\omega_3})$  bundle
  - Searching more in upstream industries would increase  $(x_{\omega_2}, x_{\omega_3})$  by less, since extra labor also needs to get hired (compared to increase in  $x_1$  from searching more in  $\omega 1$ )

#### Proposition

Under the optimal search effort, the probability of using  $\omega_1$  is

- · increasing in Hicks-neutral productivity q,
- $\cdot$  increasing in the final consumer's demand for  $\omega_0$

#### Generalizations

Extreme value math extends to any finite "production tree"

- · Any (finite) number of inputs in each stage
- · Any (finite) depth of the tree

Conditional on search effort choices, the distributions of input unit costs are EV

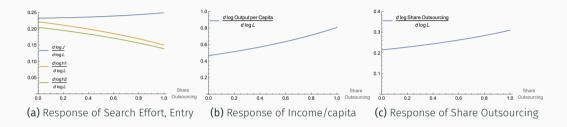

Search choices depend on Hicks-neutral productivity and upstream cost distributions

 $\Rightarrow$  solve search problem recursively starting with most upstream (leaf) nodes

#### Full Model:

- $\cdot$  (Imperfectly) elastic entry into industries  $\omega$  on a large "production tree"
- Positive profits from sales to households, marginal cost pricing to firms further downstream
- Firms born with Hicks-neutral q. Increasing returns to scale through input search.
- Potentially network economies through arrival rate of draws also depending on upstream sector characteristics.

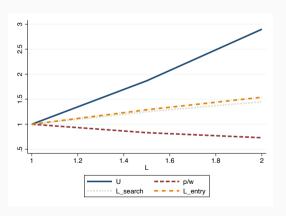

## Economy-wide increase in scale: $L \uparrow$

- $\cdot L \uparrow \Longrightarrow$  Search effort, entry  $\uparrow$
- Aggregate increasing returns to scale:  $L \uparrow \Longrightarrow u \uparrow$
- · Like IO multiplier: Response is larger if firms are more specialized
- $\cdot$  Feedback:  $L\uparrow\Longrightarrow$  more specialization  $\Longrightarrow$  Larger response

# An Economy-wide increase in scale

Figure 2: Counterfactual increase in size of the economy L

#### Conclusion

#### How do firms organize their vertical activities?

What are the implications for relationship between specialization and growth?

- · Facts:
  - · Macro: specialization correlated with development
  - · Micro: plants with larger scales have shorter vertical spans
- Model
  - Firms that are ex-ante more productive search disproportionately more for inputs further downstream ⇒ shorter vertical span
  - · Economies of scale in production
  - · Strong link between specialization and growth

Full Model

### Demand & entry

Large number of industries  $\omega$ , each with continuum of firms producing differentiated varieties

Consumption: Representative household has standard nested CES preferences

$$u = \left(\sum_{\omega} \delta_{\omega}^{\frac{1}{\eta}} u_{\omega}^{\frac{\eta-1}{\eta}}\right)^{\frac{\eta}{\eta-1}}, \qquad u_{\omega} = \left(\int_{J_{\omega}} u_{\omega j}^{\frac{\varepsilon-1}{\varepsilon}} dj\right)^{\frac{\varepsilon}{\varepsilon-1}}, \qquad \varepsilon > \eta > 1$$

Market Structure: Firms sell to firms further downstream, and to final consumers.

- Firms price at marginal cost when selling to other firms\*
- Firms are monopolistically competitive when selling to final consumers.

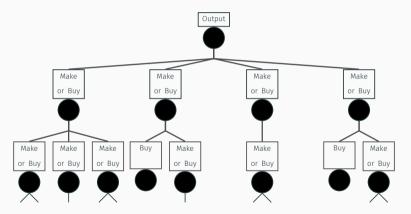

**Entry:** Representative entrepreneur chooses

$$\max \sum_{\omega} J_{\omega} \bar{\pi}_{\omega}$$
 subject to  $\left(\sum_{\omega} J_{\omega}^{\frac{1+\beta}{\beta}}\right)^{\frac{\mu}{1+\beta}} \leq 1$ 

This nests free entry  $(\beta \to \infty)$  and inelastic entry  $(\beta = 0)$  as special cases. Assume  $\beta < \infty$ .

### Production: technology menu

Each firm produces using **production modules** that make up a **production tree** (of finite depth):

The firm faces a make-or-buy decision for each non-leaf production module.

## Production modules: make-or-buy decision

A firm's **effective unit cost of input**  $\tilde{\omega}$  (in production tree) is

$$c_{j\tilde{\omega}} = \min\{c_{j\tilde{\omega}}^{o}, c_{j\tilde{\omega}}^{i}\}$$

- 1. Buy input from supplier
  - · Search effort yields set of potential suppliers,  $S_{i\tilde{\omega}}$
  - For each  $s \in S_{j\tilde{\omega}}$ : price  $p_s$  and match-specific productivity  $z_{js}$

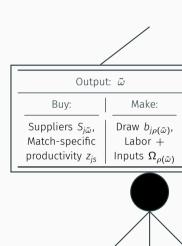

$$C_{j\tilde{\omega}}^{o} = \min_{s \in S_{j\tilde{\omega}}} \frac{p_{j}}{Z_{js}}$$

- 2. **Produce in-house** using a production module,  $\rho(\tilde{\omega})$ 
  - Module-specific productivity draw,  $b_{i\rho(\tilde{\omega})}$
  - Module prod. fct. is Cobb-Douglas in labor and inputs  $\hat{\Omega}_{\rho(\tilde{\omega})}$

$$c^i_{j\check{\omega}}=rac{1}{b_{j
ho(\check{\omega})}}w^{lpha^{
ho(\check{\omega})}_\ell}\prod_{\check{\omega}\in \dot{\Omega}_{
ho(\check{\omega})}}c^{lpha^{ho(\check{\omega})}_{j\check{\omega}}}_{j\check{\omega}}$$
tput  $\omega$  is

Firm's effective unit cost for its output  $\omega$  is

$$c_{j\omega} = \frac{1}{q_j} w^{\alpha_\ell^{\rho(\omega)}} \prod_{\hat{\omega} \in \hat{\Omega}_{\rho(\omega)}} c_{j\hat{\omega}}^{\alpha_{\hat{\omega}}^{\rho(\omega)}}$$

## Production modules: make-or-buy decision

A firm's **effective unit cost of input**  $\tilde{\omega}$  (in production tree) is

$$c_{j\tilde{\omega}} = \min\{c_{j\tilde{\omega}}^{o}, c_{j\tilde{\omega}}^{i}\}$$

#### 1. Buy input from supplier

- · Search effort yields set of potential suppliers,  $S_{i\tilde{\omega}}$
- For each  $\mathbf{s} \in S_{j\tilde{\omega}}$ : price  $p_{\mathbf{s}}$  and match-specific productivity  $z_{j\mathbf{s}}$

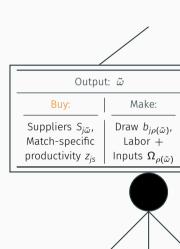

$$C_{j\tilde{\omega}}^{o} = \min_{s \in S_{j\tilde{\omega}}} \frac{p_j}{Z_{js}}$$

- 2. **Produce in-house** using a production module,  $\rho(\tilde{\omega})$ 
  - Module-specific productivity draw,  $b_{i\rho(\tilde{\omega})}$
  - Module prod. fct. is Cobb-Douglas in labor and inputs  $\hat{\Omega}_{\rho(\tilde{\omega})}$

$$c_{j\bar{\omega}}^{i} = \frac{1}{b_{j\rho(\bar{\omega})}} w^{\alpha_{\ell}^{\rho(\bar{\omega})}} \prod_{\bar{\omega} \in \hat{\Omega}_{\rho(\bar{\omega})}} c_{j\bar{\omega}}^{\alpha_{\bar{\omega}}^{\rho(\bar{\omega})}}$$

Firm's effective unit cost for its output  $\omega$  is

$$c_{j\omega} = \frac{1}{q_j} w^{\alpha_\ell^{\rho(\omega)}} \prod_{\hat{\omega} \in \hat{\Omega}_{\rho(\omega)}} c_{j\hat{\omega}}^{\alpha_{\hat{\omega}}^{\rho(\omega)}}$$

## Production modules: make-or-buy decision

A firm's **effective unit cost of input**  $\tilde{\omega}$  (in production tree) is

$$c_{j\tilde{\omega}} = \min\{c_{j\tilde{\omega}}^{o}, c_{j\tilde{\omega}}^{i}\}$$

- 1. Buy input from supplier
  - · Search effort yields set of potential suppliers,  $S_{i\tilde{\omega}}$
  - For each  $\mathbf{s} \in S_{j\vec{\omega}}$ : price  $p_{\mathbf{s}}$  and match-specific productivity  $z_{j\mathbf{s}}$

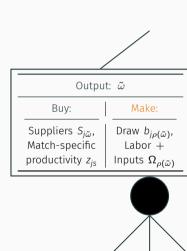

$$c_{j\tilde{\omega}}^{o} = \min_{s \in S_{j\tilde{\omega}}} \frac{p_{j}}{z_{js}}$$

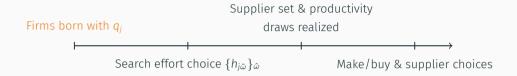

- 2. Produce in-house using a production module,  $\rho(\tilde{\omega})$ 
  - Module-specific productivity draw,  $b_{i\rho(\tilde{\omega})}$
  - Module prod. fct. is Cobb-Douglas in labor and inputs  $\hat{\Omega}_{\rho(\tilde{\omega})}$

$$c_{j\tilde{\omega}}^{i} = \frac{1}{b_{j\rho(\tilde{\omega})}} W^{\alpha_{\ell}^{\rho(\tilde{\omega})}} \prod_{\tilde{\omega} \in \hat{\Omega}_{\rho(\tilde{\omega})}} c_{j\tilde{\omega}}^{\alpha_{\tilde{\omega}}^{\rho(\tilde{\omega})}}$$

Firm's effective unit cost for its output  $\omega$  is

$$c_{j\omega} = \frac{1}{q_j} w^{\alpha_\ell^{\rho(\omega)}} \prod_{\hat{\omega} \in \hat{\Omega}_{\rho(\omega)}} c_{j\hat{\omega}}^{\alpha_{\hat{\omega}}^{\rho(\omega)}}$$

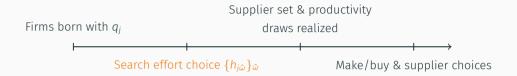

- 1. Firms born with  $q_j$ .

  Assume distribution of birth productivities has sufficiently thin tail
- 2. **Search.** Assume isoelastic and additive search cost, then the firm chooses search efforts  $\{h_{i\hat{\omega}}\}_{\hat{\omega}}$  to maximize

$$\max_{\{h_{j\hat{\omega}}\}_{\hat{\omega}\in\hat{\Omega}_{\rho(\omega)}^{\infty}} E\left[\pi_{j}|q_{j},\{h_{j\hat{\omega}}\}_{\hat{\omega}}\right] - \sum_{\hat{\omega}} \frac{k}{1+\gamma} h_{j\hat{\omega}}^{1+\gamma}$$

- 1. Firms born with  $q_j$ .
  Assume distribution of birth productivities has sufficiently thin tail
- 2. Search. Assume isoelastic and additive search cost, then the firm chooses search efforts  $\{h_{i\hat{\omega}}\}_{\hat{\omega}}$  to maximize

$$\max_{\{h_{j\hat{\omega}}\}_{\hat{\omega}\in\hat{\Omega}_{\rho(\omega)}^{\infty}} E\left[\pi_{j}|q_{j},\{h_{j\hat{\omega}}\}_{\hat{\omega}}\right] - \sum_{\hat{\omega}} \frac{k}{1+\gamma} h_{j\hat{\omega}}^{1+\gamma}$$

3. Productivity/supplier draws. If firm j chooses search effort  $h_{j\hat{\omega}}$  for input in the production tree, number of supplier with match-specific productivity greater than z is Poisson with mean

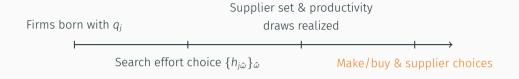

$$h_{i\hat{\omega}}m(J_{\hat{\omega}})z^{-\zeta}$$

Log of module/task productivity  $b_{j
ho}$  drawn from dist with characteristic function

$$\frac{\Gamma(1-\zeta it)}{\prod_{\hat{\omega}\in\hat{\Omega}_{\rho}}\Gamma(1-\alpha_{\hat{\omega}}^{\rho}\zeta it)}$$

Distribution is backward engineered to help with discrete choice.

4. Make/buy & supplier choice to minimize ex-post cost (⇔ maximize profit)

3. **Productivity/supplier draws.** If firm j chooses search effort  $h_{j\hat{\omega}}$  for input in the production tree, number of supplier with match-specific productivity greater than z is Poisson with mean

$$h_{i\hat{\omega}}m(J_{\hat{\omega}})z^{-\zeta}$$

Log of module/task productivity  $b_{j\rho}$  drawn from dist with characteristic function

$$\frac{\Gamma(1-\zeta it)}{\prod_{\hat{\omega}\in\hat{\Omega}_{\rho}}\Gamma(1-\alpha_{\hat{\omega}}^{\rho}\zeta it)}$$

Distribution is backward engineered to help with discrete choice.

4. Make/buy & supplier choice to minimize ex-post cost (⇔ maximize profit)

### With functional form assumptions

Normalize w = 1. Then the **distribution of unit cost of an input**  $\tilde{\omega}$  conditional on  $\{h_{j\hat{\omega}}\}$  is Weibull:

$$P\left(c_{j\tilde{\omega}}>c|\{h_{j\hat{\omega}}\}\right)=e^{-T_{j\rho(\tilde{\omega})}c^{\zeta}}$$

where

$$T_{j\rho(\tilde{\omega})} = \begin{cases} \prod_{\hat{\omega} \in \hat{\Omega}_{\rho(\tilde{\omega})}} \left( h_{j\hat{\omega}} \mathsf{v}_{\hat{\omega}} + T_{j\rho(\hat{\omega})} \right)^{\alpha_{\hat{\omega}}^{\rho}}, & \text{input nodes} \\ \prod_{\hat{\omega} \in \hat{\Omega}_{\rho(\tilde{\omega})}} \left( h_{j\hat{\omega}} \mathsf{v}_{\hat{\omega}} \right)^{\alpha_{\hat{\omega}}^{\rho}}, & \text{terminal production modules (leaves)} \end{cases}$$

where  $v_{\hat{\omega}} \equiv m(J_{\hat{\omega}}) \int_0^\infty c^{-\zeta} dF_{\hat{\omega}}(c)$  indexes the cost distribution of suppliers.

 $\Rightarrow$  Conditional on requiring input  $\tilde{\omega}$ , the probability that the firm uses a supplier for it is

$$\frac{h_{j\tilde{\omega}}\mathsf{v}_{\tilde{\omega}}}{h_{j\tilde{\omega}}\mathsf{v}_{\tilde{\omega}}+\mathsf{T}_{j\rho(\tilde{\omega})}}.$$

### Demand shocks in $\omega$

#### Proposition

If  $\delta_{\omega}$  increases (= positive demand shock),

- · more entry in industry  $\omega$ :  $J_{\omega} \nearrow$
- the price level in industry  $\omega$  falls:  $p_{\omega} \setminus (\text{and } v_{\omega} \nearrow)$
- For each input  $\hat{\omega}$ , the probability of buying it (rather than making it) increases.

### Demand shocks in $\omega$

#### Proposition

If  $\delta_{\omega}$  increases (= positive demand shock),

- more entry in industry  $\omega$ :  $J_{\omega} \nearrow$
- the price level in industry  $\omega$  falls:  $p_{\omega} \setminus (\text{and } v_{\omega} \nearrow)$
- For each input  $\hat{\omega}$ , the probability of buying it (rather than making it) increases.

#### Intuition:

- (1)  $\delta_{\omega} \nearrow \Rightarrow \bar{\pi}_{\omega} \nearrow \Rightarrow J_{\omega}$
- (2)  $\delta_{\omega} \nearrow \Rightarrow \bar{\pi}_{\omega} \nearrow \Rightarrow$  search efforts  $\nearrow \Rightarrow p_{\omega} \searrow$
- (3) Firms shift search effort toward more downstream suppliers

# Demand shocks in upstream industry $\hat{\omega} \in \hat{\Omega}_{ ho(\omega)}$

### Proposition

If  $\delta_{\hat{\omega}}$  increases (= positive demand shock in the upstream industry), then if  $\gamma$  is sufficiently large (search effort not too elastic):

- more entry in industry  $\hat{\omega}$ :  $J_{\hat{\omega}} \nearrow$ ,  $v_{\hat{\omega}} \nearrow$
- the fraction of  $\omega$  firms buying  $\hat{\omega}$  increases
- $\cdot$  total sales in industry  $\omega$  increase

# Demand shocks in upstream industry $\hat{\omega} \in \hat{\Omega}_{\rho(\omega)}$

### Proposition

If  $\delta_{\hat{\omega}}$  increases (= positive demand shock in the upstream industry), then if  $\gamma$  is sufficiently large (search effort not too elastic):

- more entry in industry û: J<sub>û</sub> →, v<sub>û</sub> →
- the fraction of  $\omega$  firms buying  $\hat{\omega}$  increases
- $\cdot$  total sales in industry  $\omega$  increase

#### Intuition:

- (1) As before
  - More matches  $m(J_{\hat{\omega}}) \nearrow$
  - firms in  $\hat{\omega}$  search more  $\Rightarrow$  lower cost
- (2)  $v_{\hat{\omega}} \nearrow \text{but } p_{\omega} \searrow$ . If  $\gamma$  sufficiently large,  $v_{\hat{\omega}} \nearrow \text{dominates for all } q$ .
- (3)  $v_{\omega} \nearrow$  and  $p_{\omega} \searrow$ , and demand elastic

### Going forward

- **Differentiated vs Standardized Inputs** (preliminary) empirical patterns driven by use of differentiated inputs
- · Profits from firm-to-firm trade
  - Account explicitly for demand shocks from downstream sectors
  - · What is internalized?
- $\cdot$  Identification of scale economies through h and m

### Going forward

- Differentiated vs Standardized Inputs (preliminary) empirical patterns driven by use of differentiated inputs
- · Profits from firm-to-firm trade
  - Account explicitly for demand shocks from downstream sectors
  - What is internalized?
- Identification of scale economies through h and m

#### Conclusion:

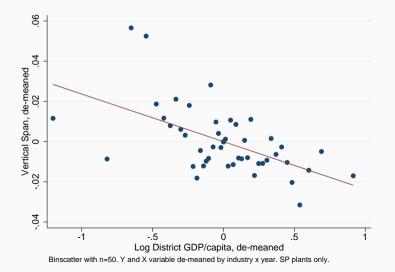

Indian Microdata suggests

- · Internal economies of scale from search
- Possibly external economies of scale through matching process

Overall, try to make progress on quantitative models of growth. How important is "Smithian" growth?

### Fact 1: In richer districts, plants are more specialized (shorter vertical span)

#### Within industry × year:

### Fact 2: Increased vertical specialization positively correlated with state growth

#### Within plant, over time:

### Details on tariff construction

We use UNCTAD tariffs, complemented by hand-digitized effective tariff rates for early vears of the liberalization (1990-1996).

- Exclude agricultural tariffs (which changed in response to domestic shocks)
- Exclude mechanical & electrical machinery (HS headings 84, 85): long list of exceptions

#### Generalizations

Extreme value math extends to any finite "production tree"

- · Any (finite) number of inputs in each stage
- · Any (finite) depth of the tree

Conditional on search effort choices, the distributions of input unit costs are EV

Search choices depend on Hicks-neutral productivity and upstream cost distributions

 $\Rightarrow$  solve search problem recursively starting with most upstream (leaf) nodes

#### Full Model:

- $\cdot$  (Imperfectly) elastic entry into industries  $\omega$  on a large "production tree"
- Positive profits from sales to households, marginal cost pricing to firms further downstream
- Firms born with Hicks-neutral q. Increasing returns to scale through input search.
- Potentially network economies through arrival rate of draws also depending on upstream sector characteristics.

### Discrete Choice Math

• Lowest cost way of acquiring good  $\omega-1$ 

$$\min \left\{ \min_{s \in S_1} \frac{p_s}{z_s} , \frac{1}{b_2} \min_{s \in S_2} w^{1-\alpha} \left( \frac{p_s}{z_s} \right)^{\alpha} \right\}$$

• Arrival of suppliers with  $z_{\rm s}>z$  is Poisson with arrival rate  $\propto z^{-\zeta}$ 

$$\min_{s \in S_1} \frac{p_s}{z_s} \sim Weibull(scale_1, \zeta)$$

$$\min_{s \in S_2} w^{1-\alpha} \left(\frac{p_s}{z_s}\right)^{\alpha} \sim Weibull\left(scale_2, \frac{\zeta}{\alpha}\right)$$

### Discrete Choice Math

 $\cdot$  Lowest cost way of acquiring good  $\omega-1$ 

$$\min \left\{ \min_{s \in S_1} \frac{p_s}{z_s} , \frac{1}{b_2} \min_{s \in S_2} w^{1-\alpha} \left( \frac{p_s}{z_s} \right)^{\alpha} \right\}$$

• Arrival of suppliers with  $z_{\rm s}>z$  is Poisson with arrival rate  $\propto z^{-\zeta}$ 

$$\min_{s \in S_1} \frac{p_s}{Z_s} \sim Weibull(scale_1, \zeta) \tag{1}$$

$$\min_{s \in S_2} w^{1-\alpha} \left( \frac{p_s}{Z_s} \right)^{\alpha} \sim Weibull \left( scale_2, \frac{\zeta}{\alpha} \right)$$
 (2)

$$\frac{1}{b_2} \min_{s \in S_2} w^{1-\alpha} \left( \frac{p_s}{z_s} \right)^{\alpha} \sim Weibull(scale_3, \zeta)$$
 (3)

• Follows from:

 $Z \sim \text{standard exponential}, \ Y \sim \alpha \text{-Stable} \qquad \Rightarrow \qquad (Z/Y)^{\alpha} \sim Z$ 

### Nested CES Example

Imagine the production function was a Nested CES:

$$y_{j} = q \left\{ (A_{1}h_{1}x_{1})^{\frac{\eta-1}{\eta}} + \left[ (A_{0}l)^{\frac{\phi-1}{\phi}} + (A_{2}h_{2}x_{2})^{\frac{\phi-1}{\phi}} \right]^{\frac{\phi}{\phi-1}\frac{\eta-1}{\eta}} \right\}^{\frac{\eta}{\eta-1}}$$

#### **Proposition**

If 
$$\gamma \geq \eta - 2$$
 and  $\gamma \geq \phi - 2$ , then

$$\frac{d \ln h_1}{d \ln q} > \frac{d \ln h_2}{d \ln q} \qquad \textit{iff} \qquad \eta > \phi$$

Our setting is a special case with  $\eta \to \infty$  and  $\phi \to 1$ .

### Where does the nonhomotheticity come from?

· Imagine a production function where search effort is factor-augmenting.

$$\max_{h_1,h_2} \delta g \left\{ C \left( w, \frac{p_1}{h_1}, \frac{p_2}{h_2} \right) \right\} - \frac{h_1^{1+\gamma}}{1+\gamma} - \frac{h_2^{1+\gamma}}{1+\gamma}$$

• Levels of optimal search effort are determined by cost shares:

$$0 = -\delta g' \frac{p_i}{h_i^2} C_i \left( w, \frac{p_1}{h_1}, \frac{p_2}{h_2} \right) - h_i^{\gamma}$$

- Relative elasticity of  $h_1$  vs  $h_2$  is therefore determined by relative *elasticity* of cost shares ... and these are encoded in the Morishima elasticities of substitution  $\sigma_{21}$ ,  $\sigma_{12}$
- If  $\gamma$  sufficiently large,  $d \log h_1/d \log q > d \log h_2/d \log q$  iff  $\sigma_{21} > \sigma_{12}$ .
- In particular that's satisfied when there is perfect substitutability between a nested and non-nested production function:

$$y_j = \begin{cases} q_j f(l_{j0}, x_{j1}) & \text{or} \\ q_j f(l_{j0}, g(l_{j1}, x_{j2})) \end{cases}$$

(assuming q is imperfectly substitutable...)
